TELOMY

Ten revolutionary app features nobody else ships.

Deep teardown: Oura · Whoop · Ultrahuman (Emerald + Jade + UltraSphere + PowerPlugs) · Gabit · 150.fit · Function Health · Levels · Apple Health · Fitbit. Then: ten features above the ceiling of what any of them do today.

What everyone already ships in 2026 — table stakes. Daily scores (Sleep / Readiness / Strain / Recovery). AI chat coach (Whoop Coach, Jade AI, Gabit One, UltraSphere's "Next Best Action" engine). Cycle & ovulation tracking. HRV + temp + SpO_2. Journaling with tags (caffeine, alcohol, stress). CGM integration. Blood test interpretation (Blood Vision, 150-marker Gabit, Oura's Quest/SteadyMD partnership). AFib detection (Ultrahuman). Jet lag plans. Longevity / biological age tabs. Habit coaching. All of this is now the floor, not the ceiling.

The ten features below are above that ceiling. Each one is user-visible, each addresses a gap that no top-10 competitor ships, each strengthens Telomy's architectural position (clinician-in-loop, event-tagged, DPDP-native, multi-modal), and each is designed for the launch demo moment — the thing a journalist or investor sees in the app and remembers.

---

01. The Live Clinician Sign-Off Thread

Every medical-adjacent Sinc insight carries a visible status chip: "drafted 09:14 · awaiting Dr. Priya Iyer · typically signed within 4 hours." The user watches the sign-off happen. When Dr. Iyer approves, the insight ships with her one-line note and signature. If she modifies or rejects it, the user sees that too. Full transparency into the human loop. Whoop Coach gives you AI. Jade gives you AI. Gabit One gives you AI. Only Telomy shows you the named human who read your biology this morning.

The move: The visible-clinician pattern is the single strongest trust signal in digital health. Nobody has UI-level transparency into the human review loop; everyone else hides their doctors behind the AI or doesn't have them.

02. The Receipts Button

On every insight, score, or recommendation anywhere in the app, a small Receipts chip. One tap reveals the exact data points, timestamps, population reference, model version, and confidence interval that produced the number. "Your HRV score dropped 12% — here are the 7 nights, the 2 events, the baseline window, and the comparator cohort." Oura shows you a score; Whoop shows you an index; Ultrahuman shows you a Next Best Action. None of them show you the receipts.

The move: Epistemic honesty as a UI pattern. For the longevity-literate audience — the Peter Attia / Huberman listener — this is the feature they didn't know they were missing until they see it.

03. The One-Tap N-of-1 Launcher

Log any new supplement, protocol, or behaviour change ("started magnesium 400mg at night"), and a chip appears: Run as a study? One tap converts that log into a pre-registered N-of-1 crossover trial — baseline window, on-period, washout, on-period again, with the primary biomarker auto-chosen based on the intervention. Four weeks later Sinc delivers the honest readout: Helped, No reliable signal, or Possible negative. Clinician reviews the design before activation.

The move: The scientific method as a button. No consumer app in the world turns a supplement log into a structured trial. This is Levels' event-tagging taken ten steps further — not just "did glucose change?" but "did this cause the change, with evidence?"

04. In-App DICOM Studio

Upload a DICOM file from your 2024 MRI or your last DEXA scan, and view it inline — pinch-zoom through actual slices, measure distances, flip through series, read the radiologist's note parsed and linked to specific findings. Your imaging appears on your Vault timeline as first-class data alongside your biomarkers. No other longevity app ingests imaging. Function sends you a PDF. Oura ignores it. Ultrahuman ignores it. Gabit ignores it.

The move: The "serious" longevity user already has imaging history — they are the exact segment with highest LTV. For them, this one feature decides whether Telomy is their Vault or just another dashboard.

05. The Confidence Gradient UI

Every number on every screen is coloured by evidence strength. A biomarker inferred from 3 data points renders at low saturation; the same marker at 30 data points renders fully saturated in teal. A Sinc insight based on 5 events shows a subtle pale border; the same pattern after 12 events shows a saturated border. The user learns to trust the colour before the number. This is epistemic honesty baked into the visual system itself.

The move: A design-system-level innovation nobody can casually copy — they would need to rebuild their entire data pipeline to attach confidence to every value. For press, this is the quotable visual: "the app that admits what it doesn't know."

06. Vault Rewind — Time-Travel Through Your Biology

A persistent slider at the top of the home screen. Drag back to any date — 15 March 2026 — and the entire home screen rewinds to that day. Your HRV, your sleep score, your Sinc insights of that morning, the events you logged that evening, the lab results you had on file, the protocol you were on. Not a chart. The actual home screen as it existed. Scroll back a year to see who you were. Nobody does this.

The move: A retention weapon disguised as a feature. Users return daily to the app anyway; users return weekly to Vault Rewind to see themselves changing. It also generates share-worthy moments — "look at my HRV in October 2024 vs October 2026."

07. The Family Vault — Scoped, Time-Boxed, Revocable Sharing

Grant a specific person (your spouse, your adult daughter, your father's caregiver, a visiting cardiologist) scoped access to specific parts of your Vault for a specific duration. "Priya can see my sleep and HRV for the next 30 days. Rohit can see my cardiac markers for 7 days. Dr. Sharma can see everything for the next 72 hours for my appointment." Fully granular, revocable in one tap, every access logged. DPDP-grade consent architecture made user-friendly.

The move: This is the feature that converts solo users into households. It is also the honest implementation of DPDP consent at a product level — most apps bury consent in settings; Telomy turns it into a feature people actually use.

08. The Pre-Clinic Brief Generator

Before any scheduled appointment — your cardiologist, your gynaecologist, your primary GP, anyone — tap Generate pre-clinic brief. Sinc produces a one-page PDF: your 30-day summary, your relevant biomarkers, your medication log, your recent events, your current protocol, and the three specific questions worth asking at this visit. HL7/FHIR-structured underneath, print-ready on top. The specialist walks in informed. The visit starts at minute three, not minute zero.

The move: This is the inter-provider workflow that nobody has built. Telomy becomes useful not just inside your Telomy clinic — but at every other clinic you ever visit. It makes the user Telomy's advocate at every medical touchpoint in their life.

09. The Protocol Marketplace

A curated store of clinician-authored protocols — "Dr. Gupta's inflammation reset," "Dr. Kaur's post-pregnancy recovery stack," "Dr. Mehta's HRV rehabilitation." Browse by goal, by clinician, by evidence rating. Buy a protocol (one-time or subscription), and it auto-personalises against your Vault — doses adjusted for your baselines, biomarker checks scheduled, your assigned Telomy clinician reviews the fit before activation. Clinicians earn royalties on uptake.

The move: iOS App Store for health protocols — a new monetisation surface and a new flywheel. Clinicians have an incentive to publish; users have discovery of real expertise; Telomy owns the platform. Nobody has shipped this.

10. The Research Contribution Dashboard

A dedicated screen that shows every Telomy Labs preprint your consented, anonymised data has contributed to. "Your sleep data was part of a 1,247-participant cohort cited in bioRxiv paper #2026.11.034. Your Halo session data contributed to a Nature preprint on adaptive PBM. You can see the papers, the findings, the download counts." Users move from being tracked to being citable. For users who opt in to research consent, the app becomes a continuous, visible act of scientific contribution.

The move: The ethical answer to the health-data extraction model everyone else runs silently. Users see what they are contributing to. It converts privacy anxiety into pride. For press and investors, it is the proof point that "Telomy publishes" is a real sentence, not a slogan.

The pattern across all ten *Every feature above does one of three things: makes the human loop visible (01, 07, 08), makes the science visible (02, 03, 05, 10), or makes new data types usable (04, 06, 09). The common thread — Telomy's app is the only one where the user*

> *can see exactly what is being inferred, by whom, from what data, with what confidence, contributing to what research, under what consent. That is not a feature. That is a category.*

Where human biology becomes intelligent.
