TELOMY

Ten features to build next. To be the best in the world.

Grounded in the 05-Oct-2026 QA audit (v1.25.0, 263 screens, zero crashes) and a competitor deep-dive across Oura (3-tab AI redesign, Cumulative Stress, Veri/Dexcom), Ultrahuman (Emerald + Jade + UltraSphere + PowerPlugs), Whoop (Coach, Journal, Weekly Plan), Gabit (150-marker, Gabit One, Clan), 150.fit, Function Health, Levels, Apple Health, Fitbit.

The audit's honest verdict in two sentences. Telomy v1.25.0 is architecturally clean (zero crashes in 50 min, 390 ms cold start, zero banned brand words, proper medical disclaimers, model versions surfaced, confidence percentages visible) and brand-compliant to a degree competitors are not. But eight of the ten roadmap features from Telomy_10_App_Features are NOT PRESENT or PARTIAL, Sinc is five preset chips with no LLM wired, the marketplace is hardcoded fake listings, data export dumps JSON to the clipboard, the APK is debug-signed, and sample preview data silently blends into the real Biological Age score.

The strategic read. The chassis is ready. The differentiators are not yet in. The next ten features turn Telomy from a well-built health app into the world's only longevity platform designed around auditable biology — with a plan that both ships new USPs AND fixes the three audit P0s productively (not as patches, as features).

---

01. The Provenance Chip on Every Number

Every single number on every screen carries a tiny inline chip: "manual · 10 min ago", "ring · last sync 2h", "lab · 03 Sep 2026", "inferred from HRV · 68% confidence". Users long-press to see the full provenance card: who recorded it, with what instrument, under what consent, used in which score. This is the structural fix for the audit's critical finding — Biological Age 27.9 mixing real BMI with sample sleep. If every number is sourced, blending becomes impossible.

Why nobody else does this: *Oura, Whoop, Ultrahuman, Gabit all show composite scores without per-value sourcing. Function Health labels inputs by lab batch, not by every value in the UI. Nobody tags provenance at pixel level — it requires the data layer to carry source as a first-class attribute, which forces an architecture choice at the schema level.*

What the audit shows: *The build already surfaces "Model longiscore-v1.0.0 / Missing: HRV, Resting heart rate" on LongiScore detail. Extending that same honesty primitive to every value turns an existing debt (sample data blending) into Telomy's signature trust feature.*

02. The Confidence Gradient — Actually Colored

The audit records "Coverage 0%, Confidence 20%" as text labels. Promote these to the visual language: a biomarker inferred from 3 nights renders at low saturation; the same marker at 30 nights renders fully saturated in teal. A score with 3% confidence shows a pale copper ring; the same score at 80% confidence shows a saturated ring. The number is accompanied by its confidence as colour, not just as a percentage you have to find.

Why nobody else does this: *Every competitor shows scores as bold confident numbers regardless of how much data backs them. Whoop Recovery 42%, Oura Readiness 71, Ultrahuman Movement Index 56 — all presented identically whether built on 2 data points or 200. The visual language itself encodes false certainty.*

What the audit shows: *LongiScore already shows "Coverage 10% / Confidence 3%" numerically. The screen's biggest visual element is still the score. Inverting that — making saturation the dominant signal — fixes the audit's implicit concern that users will trust early-stage scores too much.*

03. The Life-Event Overlay — Biology in Context

Any major life event (job change, bereavement, moved city, started medication, had a child, divorce, surgery, pandemic lockdown, travel abroad, new relationship) is a first-class entry on the Vault and overlays as a vertical band on every biomarker chart. HRV dropped in October? There's a visible overlay — your father was hospitalised that week. Chart interpretation stops being purely numeric and starts being biographical.

Why nobody else does this: *Oura has basic tags (caffeine, alcohol). Ultrahuman has activity labels. Whoop has Journal. Nobody treats life events as first-class, overlaid across every chart, every time. The closest competitor is Levels' meal tagging — but that's within a single stream (glucose).*

What the audit shows: *The audit found "Life events & daily logs" already in the Timeline — but it's a flat list, not an overlay. The data model exists; the visualisation layer doesn't. This is a 2-week engineering lift that creates a demo moment competitors cannot replicate in a quarter.*

04. The Daily Reflection — Qualitative in the Vault

A single once-a-day prompt on Home: "One thing worth remembering about today?" Short-form text, voice-to-text optional, 60 seconds. Stored as context in the Vault. When Sinc generates insights, it references these reflections ("You mentioned a difficult meeting on Tuesday — HRV reflected that evening"). Six months in, the Vault has not just your biology but a short narrative of the year that produced it.

Why nobody else does this: *Every competitor logs numbers. Nobody captures the sentence that explains the numbers. Whoop Journal is checkbox-tagging; it is not reflection. Oura has no qualitative capture. Gabit has none. 150.fit has none. The absence is a category-wide blind spot — biology without biography.*

What the audit shows: *The audit flagged that "How you feel" is actually a body-measurement form (asks for waist circumference and body fat). The qualitative slot is already there in the UI concept but misimplemented. Replacing it with a true reflection is a small build with disproportionate retention impact — users return to see what they wrote.*

05. The Pending-Clinician Queue — Even Without a Clinician

On every medical-adjacent insight, show the clinician-review architecture even for solo users: "If a Telomy clinician were on your panel, this draft would be queued for sign-off within 4 hours. [Add a clinician — ₹10k/month] or [Request a one-time review — ₹499]." This teaches the clinician-in-loop pattern before the full clinician layer is live, converts the audit's P0 (fake marketplace) into a legitimate revenue stream, and gives the user a visible glimpse of the architectural moat.

Why nobody else does this: *Ultrahuman Jade, Whoop Coach, Gabit One all give you AI output as finality. Nobody shows the user the architectural pattern of pending clinician review, because nobody has the clinician panel to deliver on it. Telomy already has 50+ Bonphul clinic installations — the panel is a real asset waiting to be used.*

What the audit shows: *The audit found the Wellness Marketplace has fake listings with hardcoded ₹1499 pricing and no payment SDK. Replace those fake listings with a real one-tap clinician review request routed to the Bonphul clinic network. The architecture already exists; the audit just revealed it's running on fiction.*

06. The Open Methods Button — The Science Visible

Every score — LongiScore, Biological Age, Readiness, Correlations — has a persistent "How this is calculated" chip. One tap opens the actual methodology: the formula, the population reference study (Levine 2018 for PhenoAge, Horvath 2013, etc.), the validation data, the honest known limitations, and the model version with git-sha. For the longevity-literate reader, this is the proof that Telomy is serious science; for everyone else, it's the ambient signal that the brand respects their intelligence.

Why nobody else does this: *Function Health hides its methods behind a brand. Gabit shows no methodology. Ultrahuman shows Jade AI outputs with no provenance to the underlying research. Oura's Readiness Score is a trade secret. Nobody shows users the actual methodology paper because nobody wants to be audited.*

What the audit shows: *The build already shows "Model longiscore-v1.0.0" and "Missing: HRV, Resting heart rate" on score detail. The methodology link is a small addition on top of an existing primitive and completes the trust loop the audit shows Telomy is already 70% toward.*

07. The Specialist Pack Generator — a Brief for Every Doctor

Not just "a pre-clinic brief" — specialty-specific briefs. Tap "I have an appointment with..." and pick: cardiologist (gets ECG + lipids + BP trends + HRV + family history + relevant medications), gynaecologist (gets cycle data + hormone trends + relevant symptoms), psychiatrist (gets sleep architecture + HRV + journal reflections + medication log), dentist (gets inflammation markers + bruxism signs + relevant history), GP (gets a full one-page summary). FHIR-compliant underneath, print-ready and QR-shareable on top. The specialist walks in informed about everything that matters to them, nothing that doesn't.

Why nobody else does this: *Nobody ships this. Function Health gives you a lab PDF. Oura gives you a wellness report. None of them tailor the brief to the specialty of the physician the user is seeing. Doctors don't want 200 markers — they want the 12 that matter for their appointment.*

What the audit shows: *The audit found "Copy weekly report" exists and dumps to clipboard with no formatting. The clipboard export is a critical privacy failure (Samsung clipboard history retains it). Specialty-tailored FHIR-compliant PDFs with QR share convert that failure into Telomy's distribution moat at every clinic in India.*

08. The Vault Completeness Score — Progress Made Visible

A persistent header number: "Your Vault is 42% complete." Tap it to see exactly what would raise it: "Connect your Dexcom → +9%. Upload your 2024 lab PDF → +5%. Add 7 more days of HRV → +4%. Enter your family history → +6%." Not gamification — architecture. Users see their biological picture coming into focus and know exactly what to do next. The anti-engagement-loop: progress toward a complete picture, not daily badges.

Why nobody else does this: *Every competitor shows a daily score (Sleep, Readiness, Recovery) and lets users return every day to see yesterday repeat. Nobody shows a long-arc completeness curve toward a definable finish state. Oura has streak-adjacent nudges. Whoop has Journal consistency. Gabit has XP. None have "your biological picture is 42% done."*

What the audit shows: *The audit found LongiScore already shows "Coverage 10%" as a leading indicator — the primitive is there. Promoting it from a per-score chip to a Vault-level persistent number is a UI change on existing data. The addition is lightweight; the behavioural effect is category-defining.*

09. The Household Dashboard — Your Family's Biology

A scoped family vault: your spouse, your parents, your adult children, your dependent minors — each with per-member granular consent (what you see of them, what they see of you), each a separate account under one household subscription. The dashboard shows aggregate household trends ("average household sleep this week: 6.8 hours — 9% below your usual"), surfaces interdependencies ("your HRV drops the week after your father's hospital visits"), and routes high-urgency insights to the right household member. Converts a solo user into a household plan.

Why nobody else does this: *Nobody has shipped the household model in longevity. Oura is strictly solo. Whoop is solo. Ultrahuman is solo. Apple Health has basic family sharing but not aggregated longevity analytics. For the Indian market — multi-generational households, elderly-care cultural norms, extended-family financial units — this is the single most structurally differentiated feature a longevity platform can ship.*

What the audit shows: *The audit shows the Family Vault from the roadmap is NOT PRESENT. The DPDP-granular consent primitives that the audit confirms Telomy already handles (per-source toggles, purpose statements, revocable access) are exactly the consent architecture a household model requires. The groundwork is laid; the feature is unbuilt.*

10. The Preprint Reader — See Where Your Data Became Science

A screen in the app that shows every Telomy Labs preprint your consented anonymised data contributed to. "Your sleep data (anonymised, part of a 1,247-participant cohort) was cited in bioRxiv paper #2026.11.034 — Adaptive PBM and REM Architecture. 423 downloads. Preprint link." Opens the actual paper. Users move from being tracked to being citable. For users who opt into research consent, the app becomes a continuous visible act of scientific contribution; for users who don't, the screen is a quiet reminder that the option exists.

Why nobody else does this: *Every longevity brand claims science. Nobody publishes it per-user. 23andMe showed users a vague "research contributions" tally with no citations. Function Health runs no in-house research. Oura has published papers but doesn't surface them per-user. The ethical answer to the health-data extraction model everyone else runs silently.*

What the audit shows: *The audit shows the Research Contribution Dashboard is NOT PRESENT and research-consent toggles don't yet exist in the build (zero research/marketing/third-party consents visible). This is a 6-week build (consent primitive + preprint registry + anonymisation pipeline + per-user attribution). For the launch narrative — "the longevity platform that publishes" — this feature is the single most quotable moment the product can give the press.*

The audit-informed strategic pattern *Four of these ten (01, 02, 06, 08) build directly on primitives the audit confirms Telomy already has — model versions, confidence numbers, coverage percentages, missing-input lists. The engineering is additive, not architectural. Three (03, 04, 07) convert existing UI concepts that misfired (life events as flat list, "How you feel" asking for waist cm, clipboard dumps) into first-class USPs. Two (05, 09) weaponise the Bonphul clinic network and DPDP-granular consent architecture that competitors structurally cannot match. One (10) is the single launch moment the brand needs.*

Build order recommendation *Weeks 1-2: 01 (Provenance Chip) + 02 (Confidence Gradient) — fixes the P0 of sample-data blending AND ships the signature trust feature. Weeks 3-4: 05 (Pending-Clinician Queue) — replaces the fake marketplace with the real one, converting a release blocker into a revenue stream. Weeks 5-6: 06 (Open Methods) + 08 (Vault Completeness) — small lifts, large signalling value. Weeks 7-8: 07 (Specialist Pack) — fixes the clipboard-export P0 productively. Weeks 9-12: 03 (Life-Event Overlay) + 04 (Daily Reflection). Weeks 13-16: 09 (Household Dashboard) + 10 (Preprint Reader) — the launch moments.*

Where human biology becomes intelligent.
